## DATA FROM FEDERAL STUDY OF SALTON SEA AREA RELEASED

---

A new report by the U.S. Department of the Interior contains data that support earlier evidence of potential toxic contaminants in the Salton Sea area. These contaminants, including selenium, are associated with irrigation drainage at concentrations that could pose a threat to human health, fish, and wildlife. A reconnaissance investigation of the area in 1986-87 led to a decision to do a more detailed study. This new report, released by the U.S. Geological Survey (USGS), presents data collected for the detailed study by the USGS and the U.S. Fish and Wildlife Service, in cooperation with the California Regional Water Quality Control Board (Colorado River Basin Region), Imperial Irrigation District, the U.S. Bureau of Reclamation, and the U.S. Bureau of Indian Affairs.

## PREFACE

The following individuals (agency affiliations are at the time of this study) participated in the collection and analysis of samples, compilation of data, and preparation of this report.

Roy A. Schroeder, U.S. Geological Survey, San Diego, California, participated in most field operations for the geochemical aspects of the study, did the laboratory experiments for tables 17 and 18, and prepared that part of this report related to tables 1-18 done by the U.S. Geological Survey.

Mick Rivera, U.S. Fish and Wildlife Service, Carlsbad, California, participated in field operations for the biological aspects of the study and prepared that part of this report related to tables 19-24 done by the U.S. Fish and Wildlife Service.

Brenda J. Redfield, U.S. Geological Survey, San Diego, California, compiled and reformatted data tables received in various forms from other agencies, offices, and individuals and assisted in the data-table verification process.

Jill N. Densmore, U.S. Geological Survey, San Diego, California, collected surface-water and ground-water quality data that are presented in tables 2, 4, 5, and 10 and that also were used by her to prepare an M.S. thesis at San Diego State University.

Robert L. Michel, U.S. Geological Survey, Reston, Virginia, obtained the tritium data presented in tables 6 and 16 and included elsewhere with additional water-quality data in various other tables.

Daniel R. Norton, U.S. Geological Survey, Denver, Colorado, analyzed soils and soil extracts that provided the data presented in tables 11-15.

Daniel J. Audet, U.S. Fish and Wildlife Service, Carlsbad, California, was the co-principal investigator with the project chief (Steven L. Goodbred) for collection of the biological data presented in tables 22 and 23.

James G. Setmire, U.S. Geological Survey, San Diego, California, served as project chief for the U.S. Geological Survey's part of this study, collected sediment and water-quality data from the Alamo River delta presented in table 7 and figure 4, and had primary responsibility for preparation of that agency's contribution to the interpretive report.

Steven L. Goodbred, U.S. Fish and Wildlife Service, Carlsbad, California, was project chief for the U.S. Fish and Wildlife Service's part of this study and had primary responsibility for preparation of that agency's contribution to the interpretive report.

# **PHYSICAL, CHEMICAL, AND BIOLOGICAL DATA FOR DETAILED STUDY OF IRRIGATION DRAINAGE IN THE SALTON SEA AREA, CALIFORNIA, 1988-90**

*By Roy A. Schroeder,<sup>1</sup> Mick Rivera,<sup>2</sup> and others*

## **Abstract**

This report contains physical, chemical, and biological data associated with irrigation drainage in the Salton Sea area collected during the late 1980's. The data were collected in support of the U.S. Department of the Interior's National Irrigation Water Quality Program in the Western United States to evaluate effects on the environment from potential toxins in irrigation-induced drainage. The data have been used to support interpretations in several recent publications. This data report is the companion to a comprehensive U.S. Geological Survey interpretive report that describes the geochemical and biological pathways of potential toxins, especially selenium, in the study area.

The report contains data on concentrations of a broad suite of trace elements in soil, irrigation (Colorado River) water, drainwater, surface water (including the Salton Sea), ground water, aquatic plants, invertebrates, amphibians, reptiles, fish, birds, bird eggs, and turtle eggs. Included, also, are light stable isotope (hydrogen, oxygen, carbon, nitrogen, and sulfur), tritium, and radio-carbon data for selected aqueous samples and organochlorine-pesticide concentrations in biota.

Geochemical samples were collected from more than 100 drainwater-collection sites, several surface-water locations, 15 fields, 3 multiple-depth lysimeter and piezometer installations, and

the Alamo River delta on the southeastern shore of the Salton Sea, and from laboratory evaporation of Colorado River water.

Biological samples were collected from 39 sites, including 16 Salton Sea shore locations, 5 streams, 7 freshwater impoundments, 11 drainwater ditches, and 2 additional locations in the Imperial Valley.

## **INTRODUCTION**

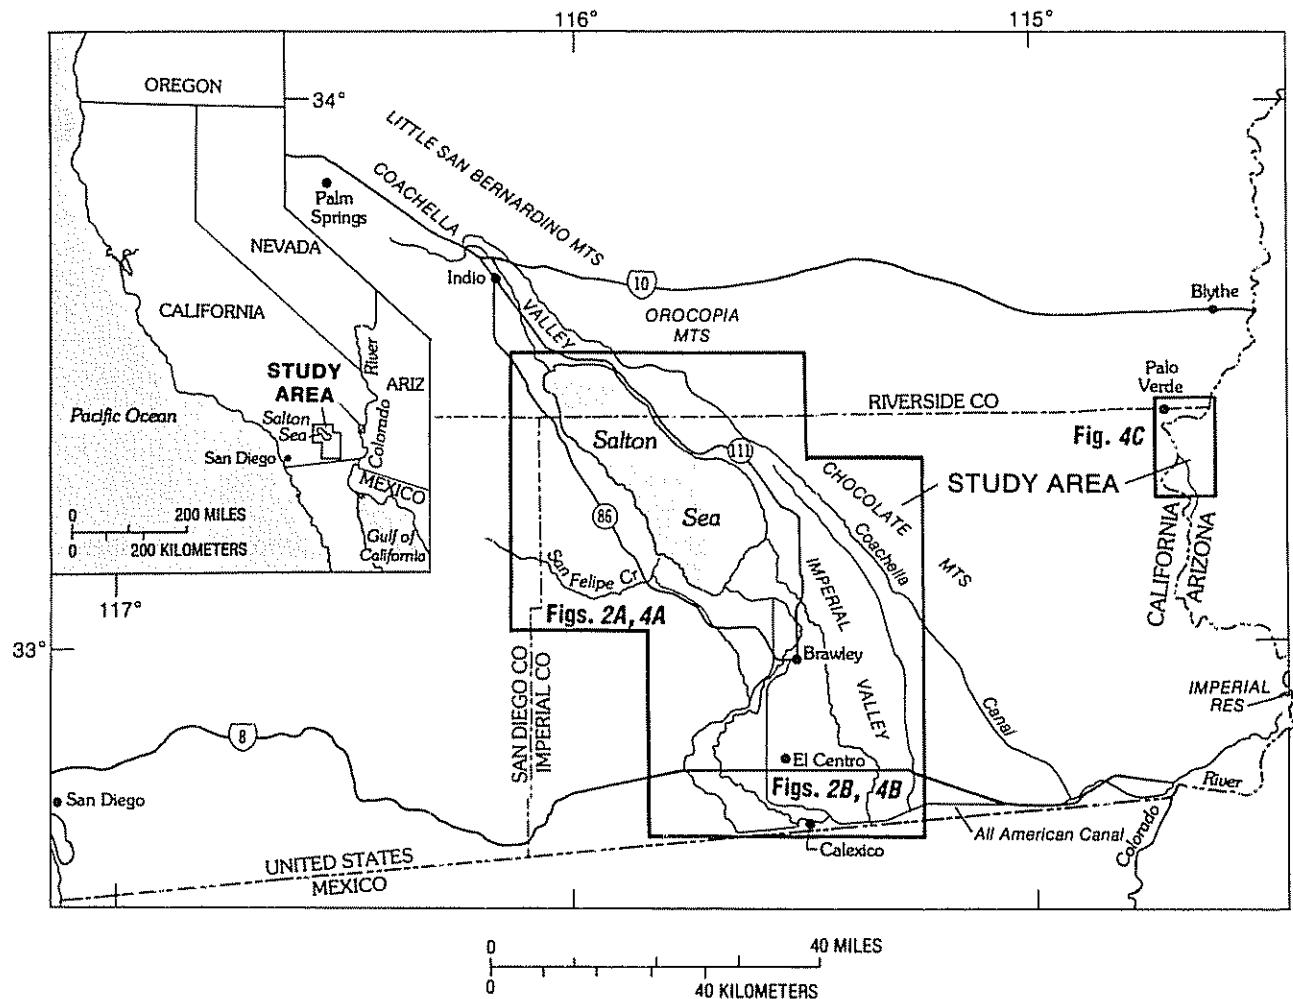

In response to concerns about irrigation-induced water-quality problems and their potential effects on biota, the U.S. Department of the Interior (DOI) began a study in the Salton Sea area, California, in 1986. The study was part of the DOI National Irrigation Water Quality Program (NIWQP). The initial phase of the Salton Sea area investigation was a reconnaissance, completed in 1987, that led to a decision to do a more detailed study in the Imperial Valley. The results of the reconnaissance were reported by Setmire and others (1990b).

This report presents the data from a detailed study done during 1988-90. The detailed study was a joint effort conducted by scientists from the U.S. Geological Survey (USGS) and the U.S. Fish and Wildlife Service (USFWS). The USGS was responsible for determining the hydrologic and geochemical factors affecting concentrations of irrigation-induced contaminants, particularly selenium, and the USFWS was responsible for identifying pathways of contaminant accumulation in biota. Results of the detailed study will be used as part of the information needed for

planning and conducting remediation efforts under direction of the U.S. Bureau of Reclamation.

#### IRRIGATION AND DRAINAGE SYSTEMS IN THE IMPERIAL VALLEY

The central part of the Imperial Valley consists of 500,000 acres of irrigated and drained farmland in the desert area of southeastern California (fig. 1). Irrigation water is obtained by gravity diversion of water from the Colorado River, via the All-American Canal, to (from east to west) the East Highline, Central Main, and Westside Main (and its Trifolium Extension) Canals (fig. 2B). These canals supply numerous smaller canals throughout the valley. Drains at a depth of 6 to 10 ft carry subsurface water containing dissolved salts to sumps at the tail end of selected fields or discharge directly to drainage ditches. All drainwater ultimately is discharged to the Salton Sea,

either directly from drainage ditches or by way of the New and Alamo Rivers.

The Alamo River discharges to the Salton Sea at the northern unit (Unit 2) of the Salton Sea National Wildlife Refuge (SSNWR), and the New River and Trifolium Drain 1 discharge at the southern unit (Unit 1) of the refuge (fig. 2A). The proportions of total discharge that originates from use within the Imperial Valley—for the New River, Alamo River, and Trifolium Drain 1—are about 50, 99, and 100 percent, respectively. Sources of discharge to San Felipe Creek (fig. 2A) are precipitation in mountains to the west and ground water.

#### PURPOSE AND SCOPE

The purpose of this report is to present all data collected during the 1988-90 U.S. Department of the

Interior detailed study of irrigation-induced contamination problems in the Salton Sea area, along with a brief description of methods, principal reasons for collecting each of the various kinds of data, and unusual or special field observations. Also included are the results from pesticide and polycyclic aromatic hydrocarbon analyses of biological tissues collected during 1986-87 that were not published (analyses had not been completed) in the reconnaissance (Setmire and others, 1990b) report. This report is intended to serve as a companion and supplement to the interpretive report of the detailed study by Setmire and others (1993) that is based on these data. Other reports and abstracts published to date on this study include Schroeder and others (1988, 1989, 1991), Michel and others (1988), Michel and Schroeder (1989), Setmire and others (1990a, b), and Densmore (1991).

#### TYPES AND NUMBERS OF SAMPLES

Analytical data for the detailed study (sampling-site locations shown in figs. 2, 3, and 4) include the following:

1. A single synoptic sampling of drainwater from 108 sites in May 1988.
2. Monthly monitoring at 15 of the 108 drainwater sites for 1 year.
3. Monthly monitoring at six surface-water locations for 1 year.
4. Single collections of surface-water samples from several sources, including the Salton Sea.
5. Ground water from multiple-depth lysimeters and piezometers at three sites.
6. Soils and water extracts of soils (soil extracts) from fields at the 15 drainwater-monitoring sites and from cores at the 3 ground-water monitoring sites.
7. Evaporation and dilution laboratory experiments.
8. Collection of 276 biological samples from 29 sites for analysis of 67 organic analytes.
9. Collection of 363 biological samples from 36 sites for analysis of 23 inorganic analytes.

#### ANALYTICAL LABORATORIES AND METHODS

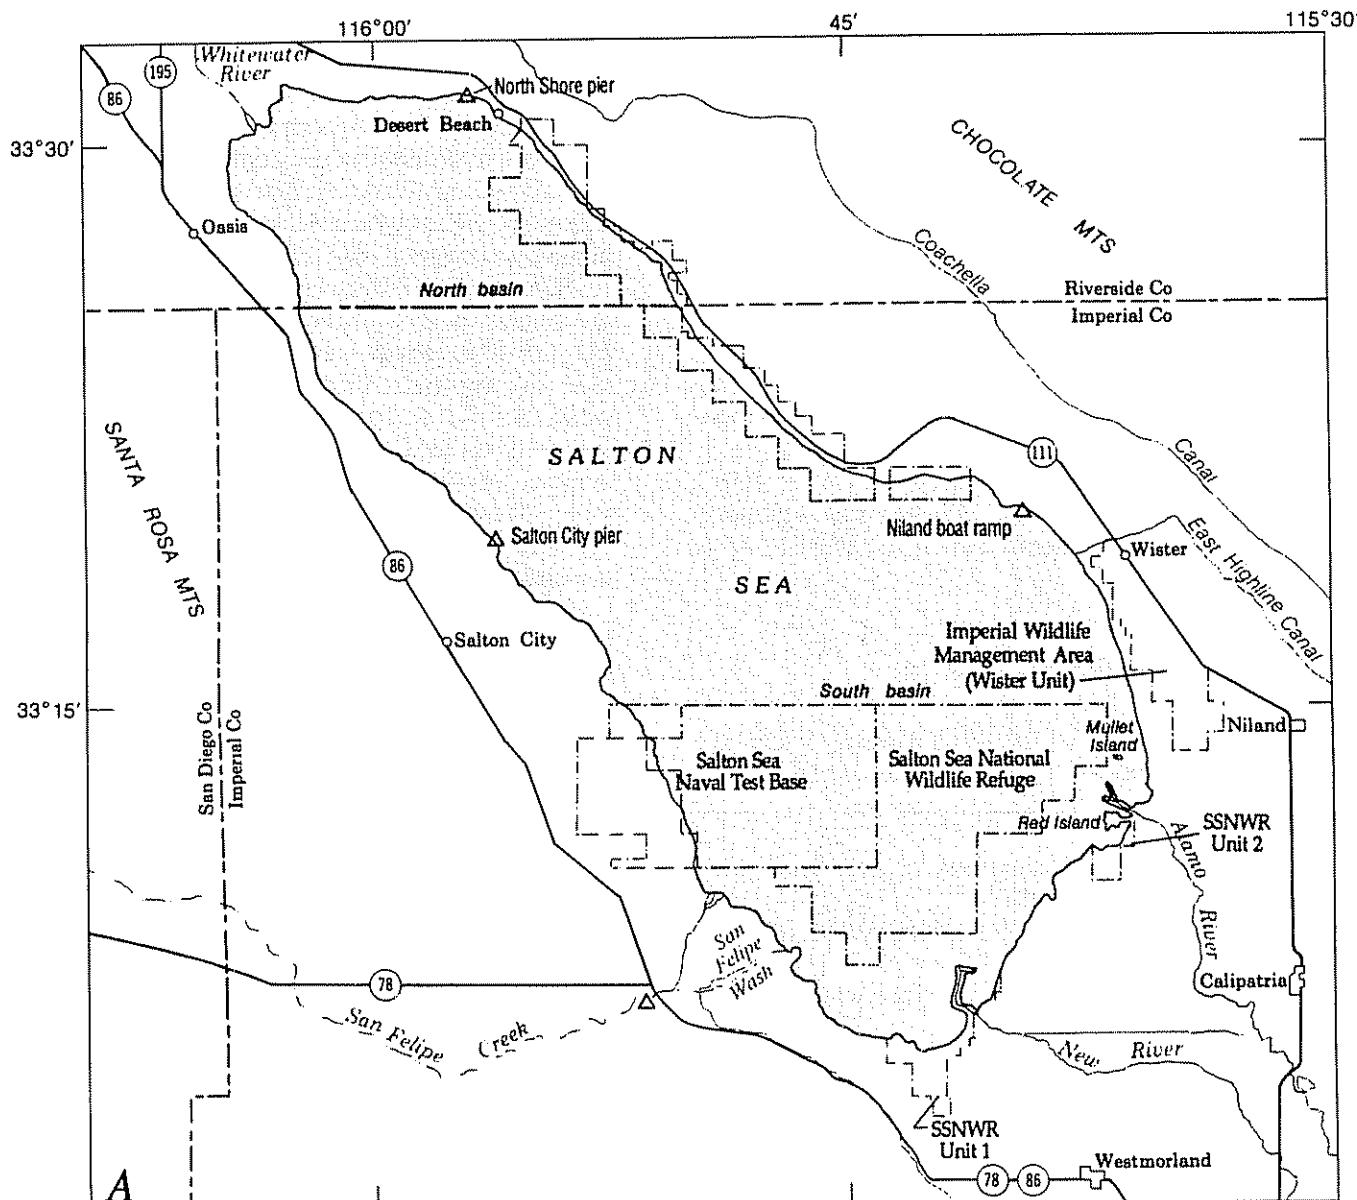

Aqueous chemical analyses were done at the USGS National Water Quality Laboratory (NWQL) in Arvada, Colorado, using methods described by Fishman and Friedman (1989) and Pritt and Jones (1989). These references also give general information on analytical sensitivity and precision for the laboratory

analyses. Stable hydrogen- and oxygen-isotopes and tritium were analyzed at the USGS Isotope Laboratory in Reston, Virginia. The stable-isotope ratios were determined by mass-spectrometry, as concentration ratios for hydrogen and as activity ratios for oxygen. Tritium was analyzed by liquid-scintillation counting following electrolytic enrichment. Other isotopes of carbon, nitrogen, and sulfur were analyzed by NWQL-contract laboratories. Precision ( $1\sigma$ ) is 0.1 to 0.2 permil for  $\delta^{13}\text{C}$ ,  $\delta^{15}\text{N}$ , and  $\delta^{18}\text{O}$ ; 1 to 2 permil for  $\delta\text{D}$  and  $\delta^{34}\text{S}$ ; about 1 percent modern carbon for  $^{14}\text{C}$  near the reporting limit; and ranges from about 1 pCi/L for  $^3\text{H}$  at concentrations near zero to about 3 percent on the basis of counting statistics at concentrations above ambient irrigation-water (Colorado River water) concentration. Stable-isotope ratios are reported in standard notation relative to ratios in commonly used standards (Fritz and Fontes, 1980).

Chemical analyses of soils and soil extracts were done by the USGS Branch of Geochemistry in Denver, Colorado. Methods for analysis of soil extracts were similar to those used by the NWQL. Analysis of extractable (readily soluble) salts was done by overnight extraction with a 5-to-1 weight ratio of deionized water to soil. Shallow-soil and core samples were stored and shipped in wide-mouth plastic containers to the laboratory, where they were prepared for analysis by drying and grinding (to pass an 80-mesh [0.18-mm] sieve), followed by complete dissolution with an oxidizing agent and strong mineral acids. Methods for analysis of soils were identical to those used by Severson and others (1987) in the reconnaissance phase of this study, and quality-assurance and analytical precision standards are given by Arbogast (1990). Forty-element scans were done by inductively coupled argon-plasma atomic emission spectrometry (ICP). Arsenic and selenium were analyzed by hydride-generation atomic absorption, and boron concentrations were determined in hot-water extracts.

Grain-size analyses of cores and shallow soils were done at the USGS Sediment Laboratory in Salinas, California, using sieves for the coarse fraction and hydrometers for the fine fraction as described by Guy (1969).

Chemical analyses of biological samples were done at contract laboratories. The contract was administered by the USFWS Patuxent Analytical Control Facility in Laurel, Maryland, which also was responsible for ensuring quality control and quality assurance. Methods used for analysis of biological samples are those prescribed in a USFWS procedures

#### EXPLANATION

Sampling site and number--

$\blacktriangledown_{97}$  Subsurface-drainwater site

$\triangle$  Surface-water site

**Figure 2.** Water-sampling sites in the study area. **A**, San Felipe Creek and Salton Sea (August 1988 sampling). **B**, Imperial Valley. Location of map areas shown in figure 1.

manual (USFWS, 1985a). Instruments and methods used for trace-element analysis (Lowe and others, 1985) are the same as those used by the USGS (Fishman and Friedman, 1989). Mercury, which was determined in biological tissues only (not in soil and water) for this study, was analyzed by cold-vapor atomic absorption. Gas-liquid chromatographic methods used

to analyze organochlorine compounds also are similar to those in use by the USGS (Wershaw and others, 1987). Polycyclic aromatic hydrocarbons on crayfish and tilapia collected in 1987 during the reconnaissance were analyzed by gas chromatography-mass spectrometry. Concentrations of constituents in biota are reported on a dry-weight basis for trace elements

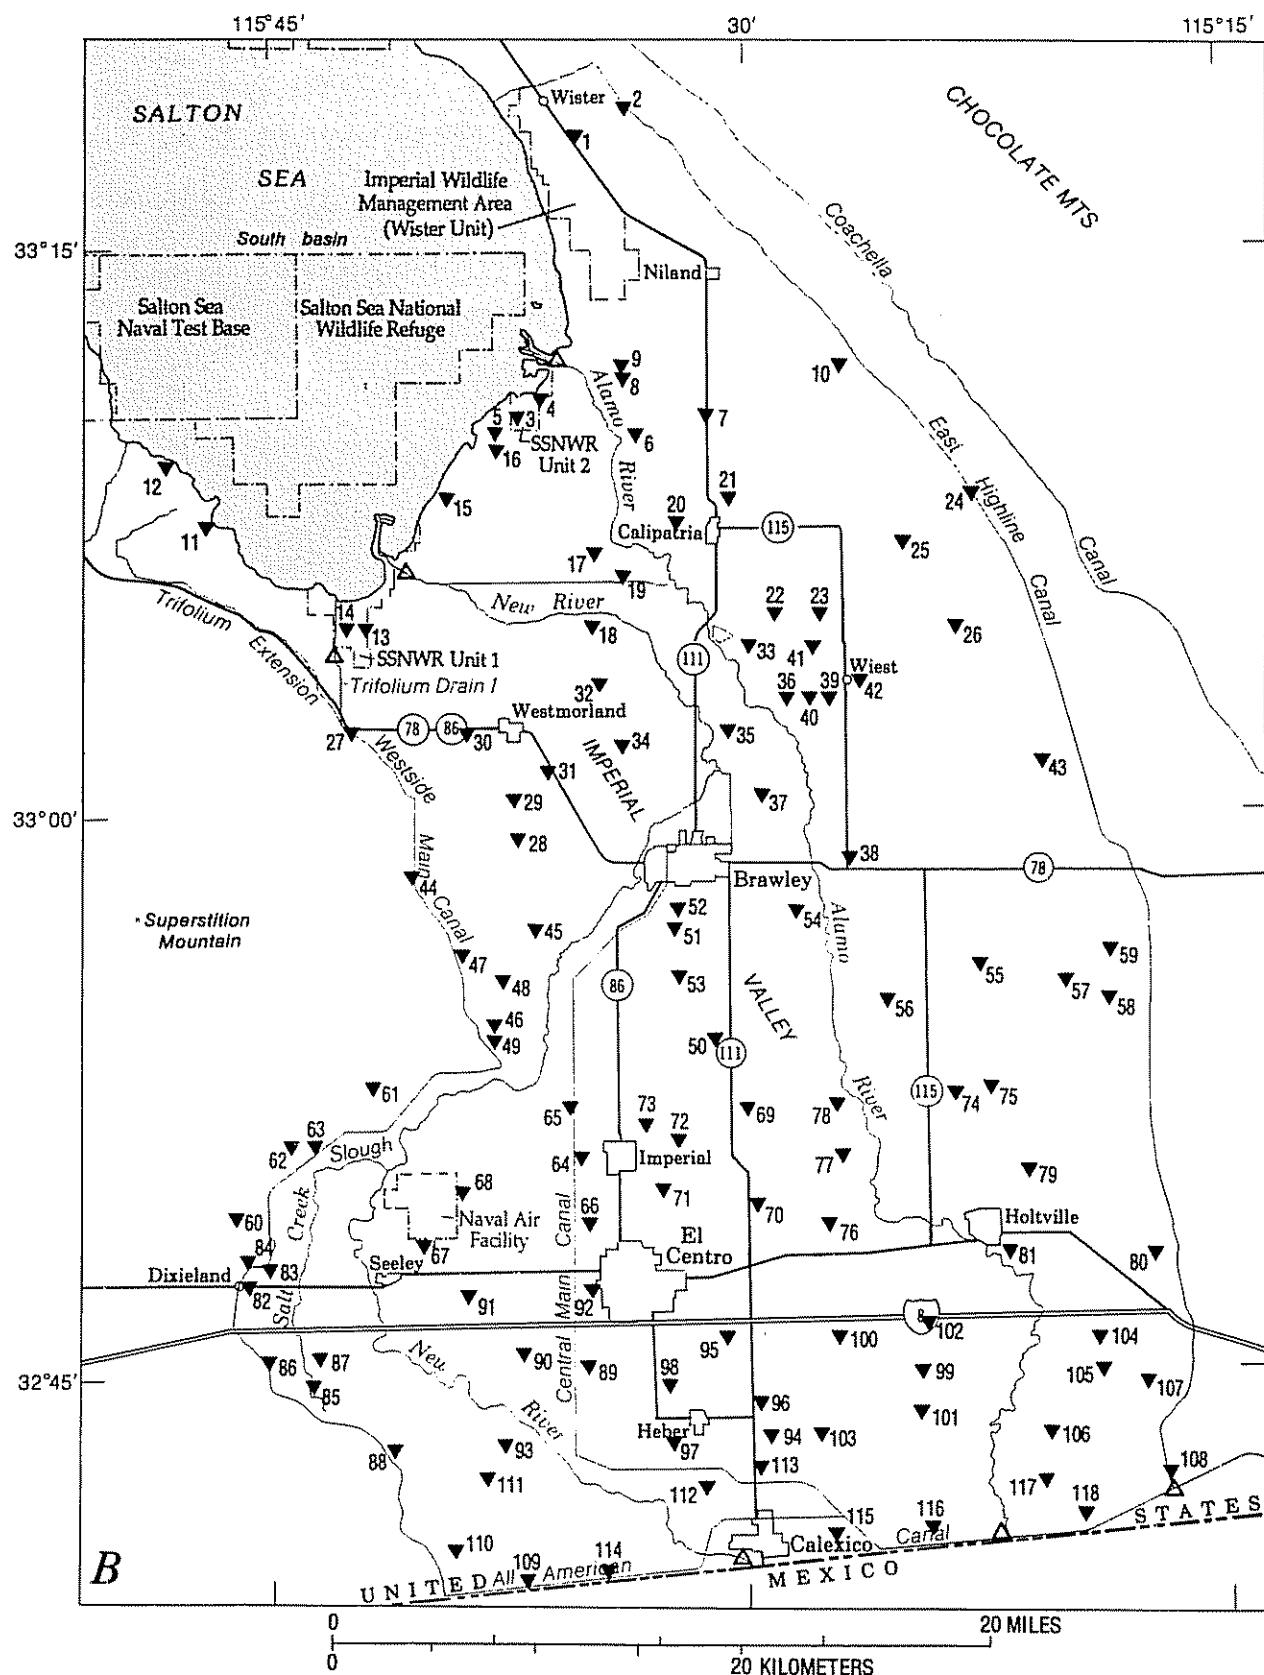

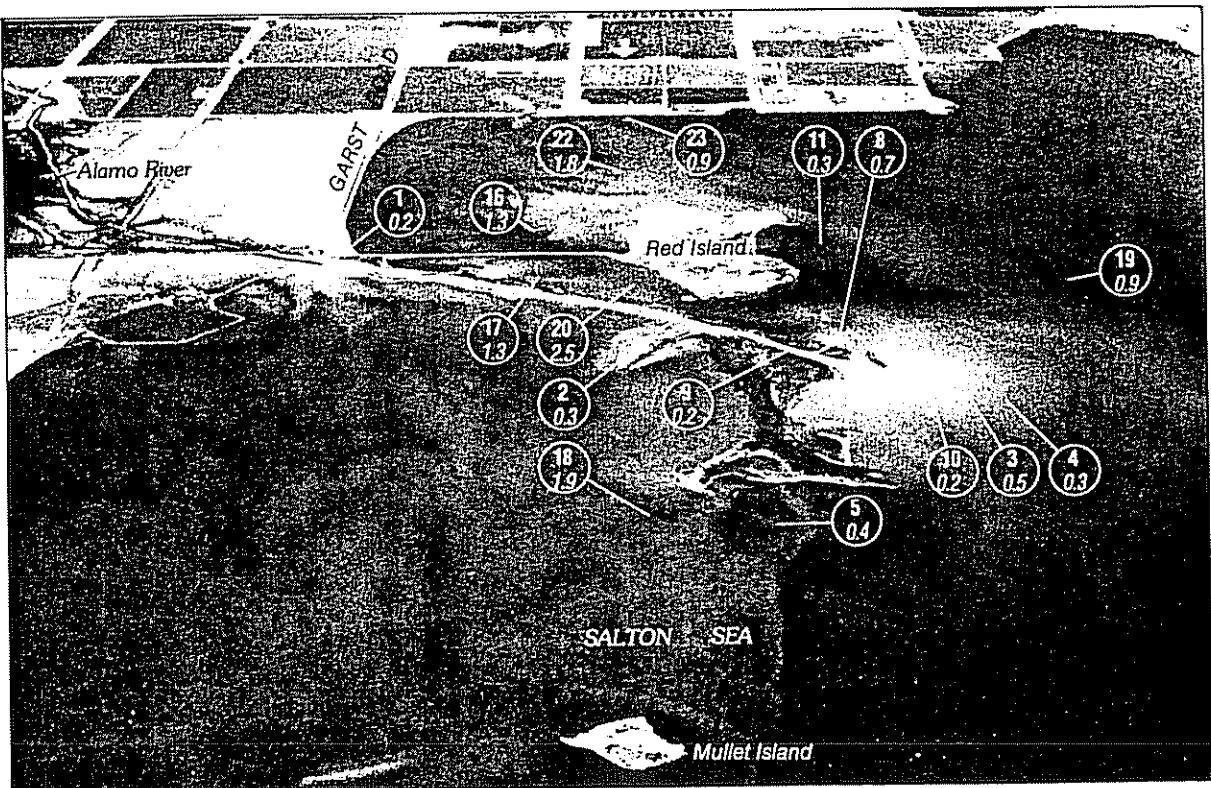

Figure 2. Continued.

#### EXPLANATION

 Site number  
 Selenium concentration—In micrograms per gram

**Figure 3.** Water- and sediment-sampling locations, and selenium concentration in surficial sediments, in the Alamo River delta.

and on a wet-weight basis for organochlorine and polycyclic aromatic hydrocarbon compounds.

To maintain internal consistency within the entire data set, results are reported herein without correction for unknown analytical or occasional transcription errors that may occur during transfer of the data into permanent computer storage. When large, such errors usually are apparent as data outliers (especially when multiple samples were collected over a period of time) and from comparisons between constituents; on the basis of cursory inspection of the data, such errors are believed to represent less than 1 percent of the data set.

#### ACKNOWLEDGMENTS

The U.S. Department of the Interior provided most of the support for this study. The authors also

thank the California Regional Water Quality Control Board, Colorado River Basin Region, for additional financial support and for field assistance with the May 1988 sampling of drainwater sites, and the Imperial Irrigation District for procuring access to sites and for assistance in the coring of shallow soils.

#### DRAINWATER DATA

The Imperial Irrigation District uses letters followed by numerals to designate drainwater-discharge sites in the Imperial Valley. The letter designations are "TD" for subsurface drains that discharge directly to a drainage ditch, "S" for sumps that collect drainwater from a network of subsurface drains at the corner of a field and then discharge to ditches, and "SS" for sumps that are adjacent to the Salton Sea. (Some sumps designated "S" also are near the Salton Sea, and a few even discharge directly to the Salton Sea.)

As of 1990, when this study was completed, 532 drainwater sums (9 of which were subsequently removed or placed out of service) had been installed in the Imperial Valley. Thirty of the sums are designated "SS." In addition, there are about 3,700 drains which are designated "TD" and which discharge directly to ditches. The first subsurface drains were installed in the Imperial Valley in 1928, and the first sum was installed in 1947. The historical pattern of sum installation is depicted in figure 5 (S.R. Knell, Imperial Irrigation District, oral and written commun., 1991). The historical pattern of subsurface-drain installation (Moore, 1991, fig. 19, p. 88) is similar to that of sum installation. The annual rates of installation are highest from the early 1950's to the early 1970's. More than 30,000 mi of subsurface drains had been installed by 1990 (Moore, 1991).

It should be noted that the term "drainwater," used during this study to refer to water in the sums, includes not only subsoil moisture from interior parts of the field, but also rapid-percolation irrigation water directly above the subsurface drains; ground water; leakage from nearby canals, ditches, and ponds; and possibly even stormwater and tailwater in unusual circumstances.

Water samples from drains that discharge directly to a ditch were obtained in a 5-gallon plastic bucket held beneath the lip of the drain. Instantaneous discharge was measured by timing the rate at which the bucket filled. Water samples from sums were obtained in a similar manner after manually activating the pump, causing the sum to discharge its contents through a pipe into a nearby ditch. Instantaneous discharge to the sum then was calculated as the sum refilled by multiplying sum diameter (90 in.) and rate at which the water level rose in the sum as measured on a vertical stem attached to the float. Accuracy of discharge measurements is estimated to be about 20 percent at most sites, and somewhat poorer at a few sites where flow to the sum was either extremely high or near zero.

Most drainwater samples were free of visible particulates. Occasional samples contained a few large particles derived from encrusted mineral deposits and soils, either in the sum itself or on the lip of the discharge pipe; such particles were readily removed from the sample by rapid gravitational settling.

#### 1988 SYNOPTIC SAMPLING AT 108 SITES

Drainwater samples were collected from 108 sites in the Imperial Valley during May 16-20, 1988, to determine spatial variation in drainwater quality and

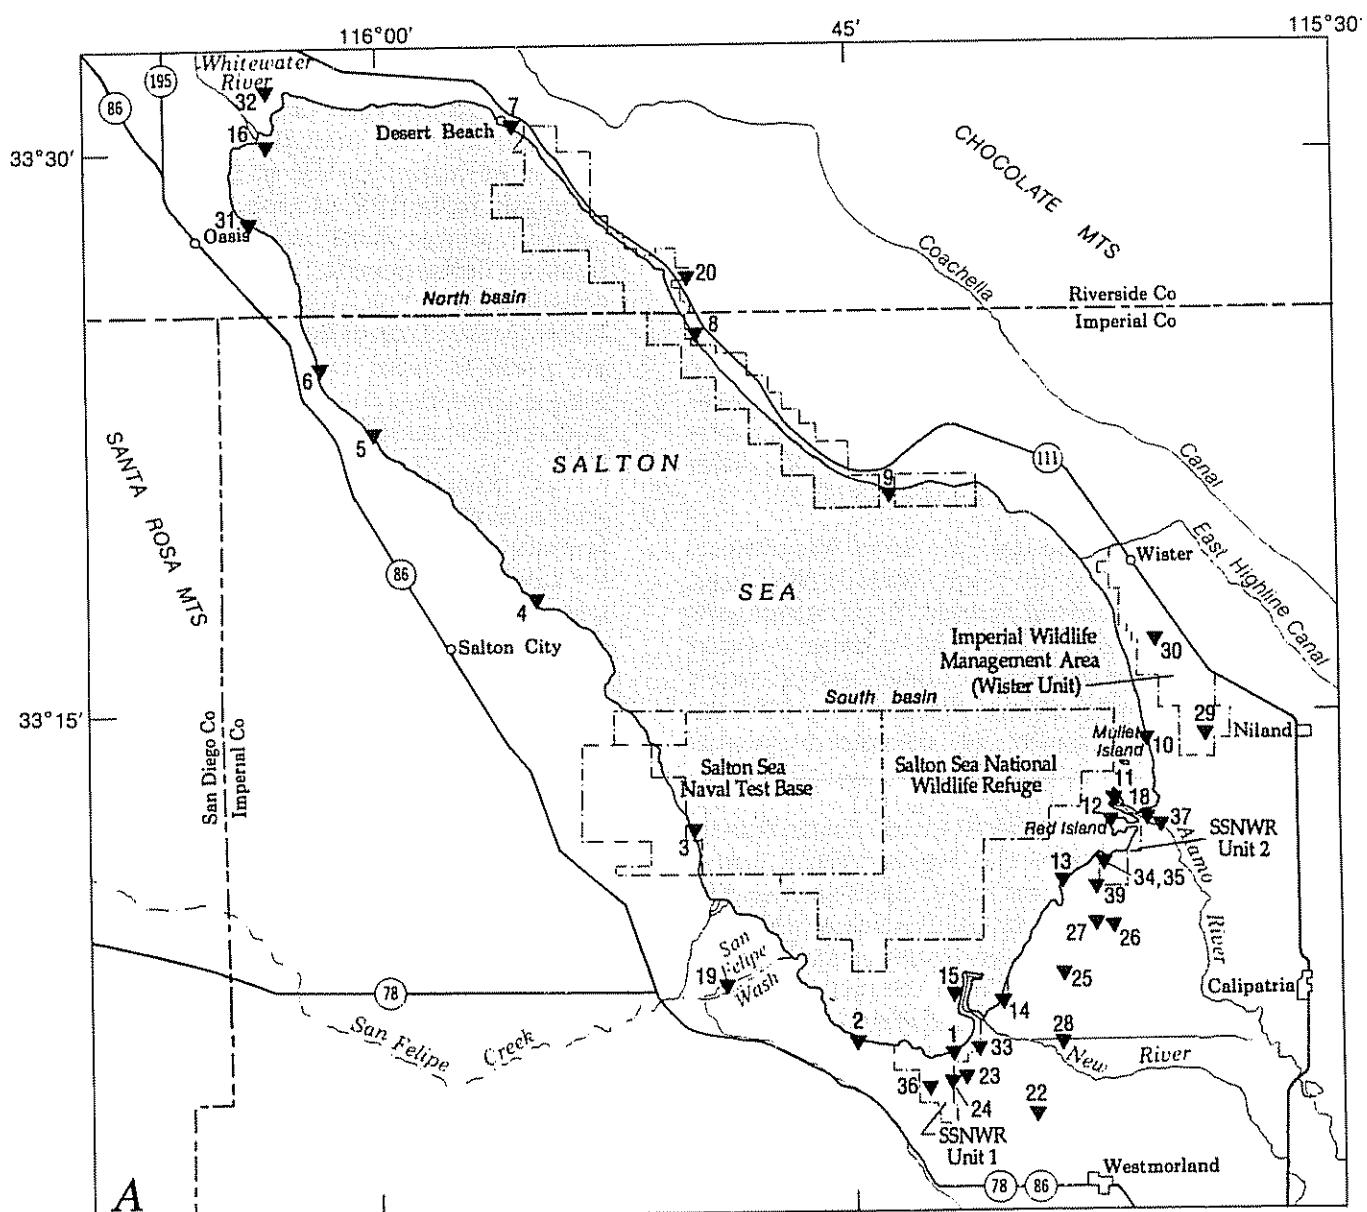

to compare with and expand on results of a similar synoptic sampling done by the California Regional Water Quality Control Board during June 24-July 10, 1986. The 1986 sampling included 119 sites that subsequently were located with the aid of Imperial Irrigation District's canal and drainage maps and USGS quadrangle maps. Eleven of the 119 sites were not resampled in the 1988 synoptic because they were no longer in service, contained no water, or could not be found by field personnel. Results from the 1986 synoptic sampling (P.A. Gruenberg, California Regional Water Quality Control Board, written commun., 1987) are given in table 1, and results from the 1988 synoptic sampling are given in table 2. The location of drainwater sampling sites is shown in figure 2B.

All drainwater samples collected from the 108 sites in May 1988 were analyzed for selenium and a few other constituents. In addition, about one-third of the samples were analyzed for a broad suite of chemical and isotopic constituents. These data are the principal basis for the conclusion that evaporation of irrigation water supplied by the Colorado River is the primary geochemical mechanism controlling selenium concentrations in Imperial Valley drainwater (Schroeder and others, 1991, and Setmire and others, 1993). Eighty percent of the sums sampled had a Se/Cl ratio ranging from 0.5 to 2 times the ratio ( $2.2 \times 10^{-5}$ ) in Colorado River water (refer to the section "Evaporations of Irrigation Water" presented later in this report). For those sums in which the ratio lies above this range, leaching of selenium from the soil is thought to be the predominant geochemical mechanism controlling selenium concentration (Schroeder and others, 1991). Only 5 percent of the sums had a Se/Cl ratio greater than  $4.4 \times 10^{-5}$ , and the highest ratio measured exceeds the ratio in irrigation water by only a factor of 3. Fifteen percent of the sums had a Se/Cl ratio less than  $1.1 \times 10^{-5}$ , and the ratios for half of these were about one-tenth the ratio in irrigation water, or less. At these sites, there exists a substantial sink for selenium believed to be the result of microbial reduction within the local field and (or) intrusion of deeper selenium-deficient ground water into shallow drains (Schroeder and others, 1991).

Drainwater samples were collected from eight sites (three sums and five tile drains) in 1986 during the reconnaissance study. Six of the eight sites were resampled in August 1988, and results from both years are given in table 3.

#### 1988-89 MONTHLY MONITORING AT 15 SITES

Samples from 15 of the drainwater-collection sites were collected monthly during 1988-89 to check for

**Figure 4.** Biological sampling sites in the study area. **A**, Salton Sea. **B**, Imperial Valley. **C**, Colorado River near Palo Verde, California. Location of map areas shown in figure 1.

temporal variations in drainwater quality and to compare the results with soils and soil-extract data from fields that drain to these sumps. The 15 sites were chosen with the intent of obtaining good areal coverage over the valley and to represent sites with moderate to high concentrations of selenium. Results from the monthly monitoring are given in table 4.

To document the expected minimal effect of filtration on most constituent concentrations, the last monthly sample, collected in August 1989, was filtered through a 0.45- $\mu\text{m}$  membrane. The results can be compared with those of unfiltered samples collected in the prior months. In addition, concentrations of selenium (and a few other constituents) were deter-

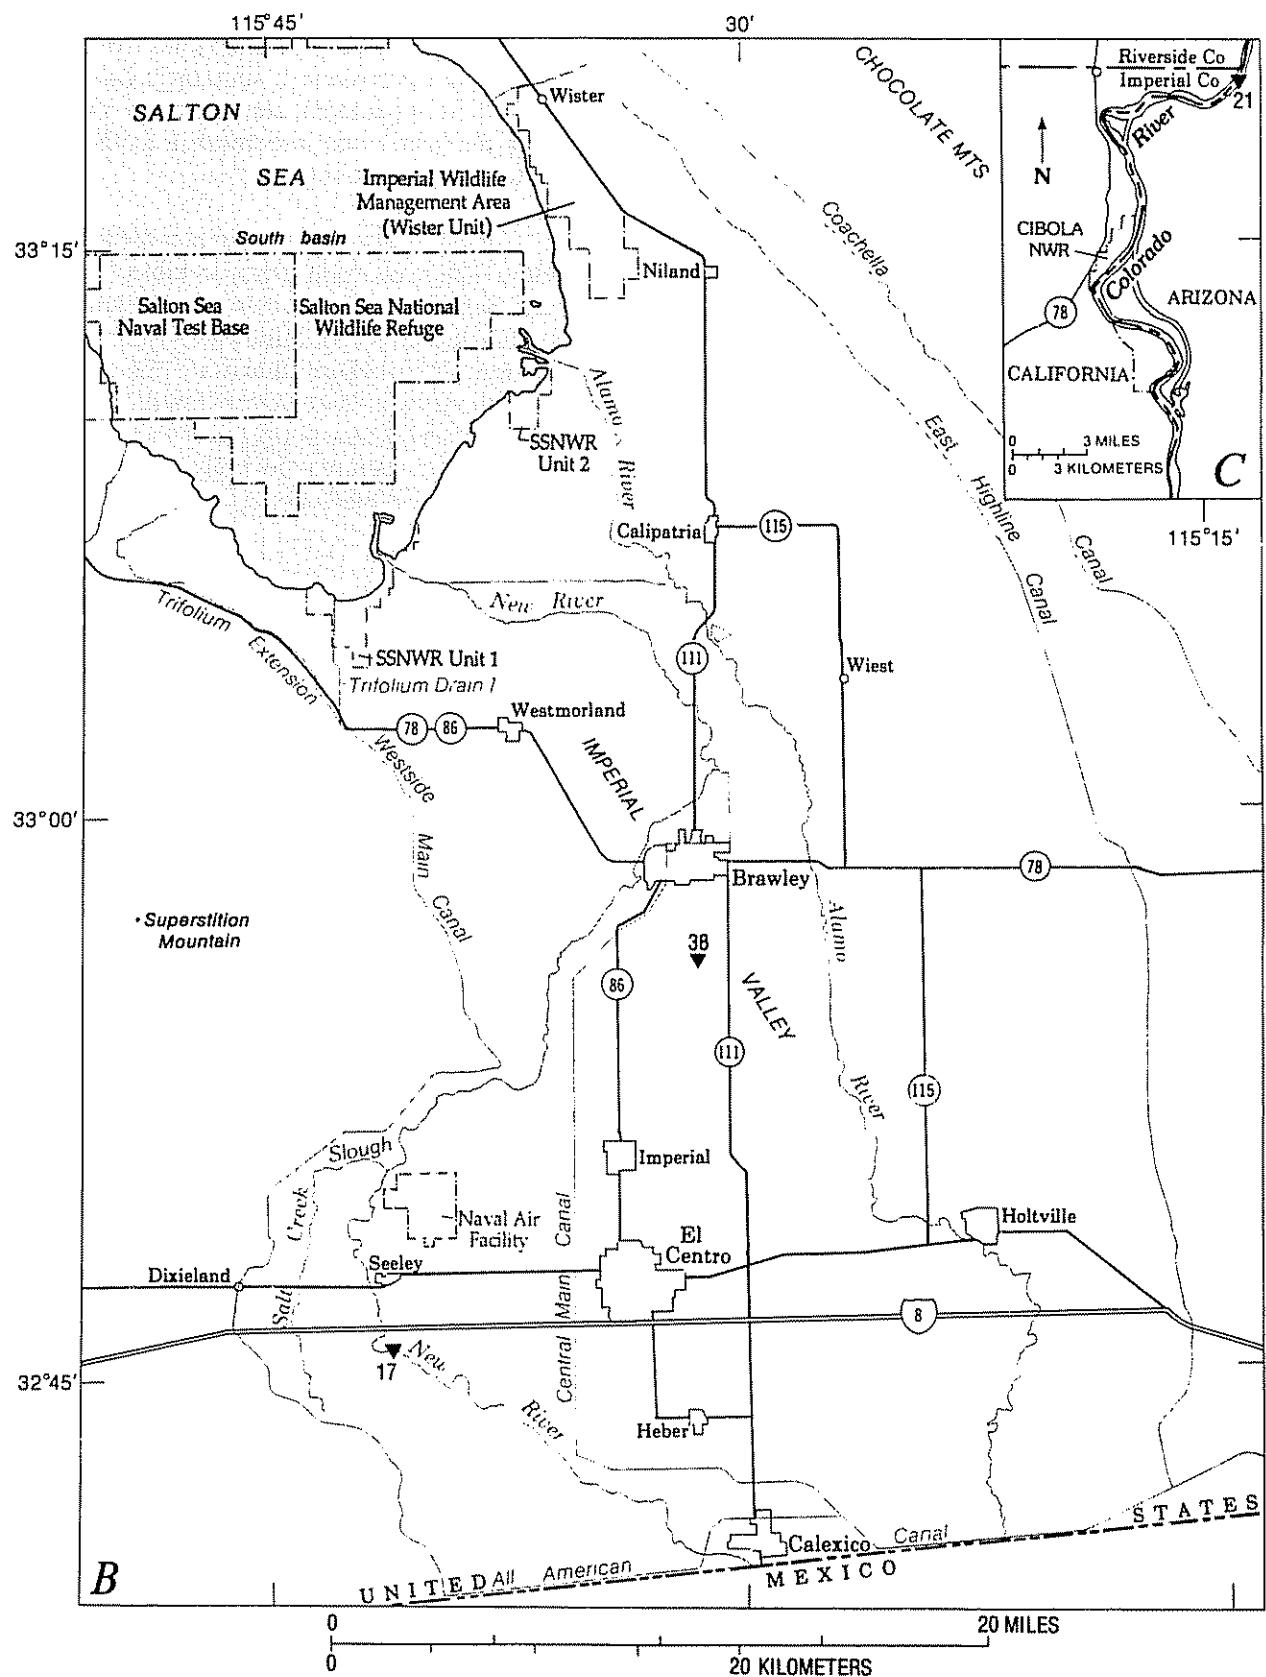

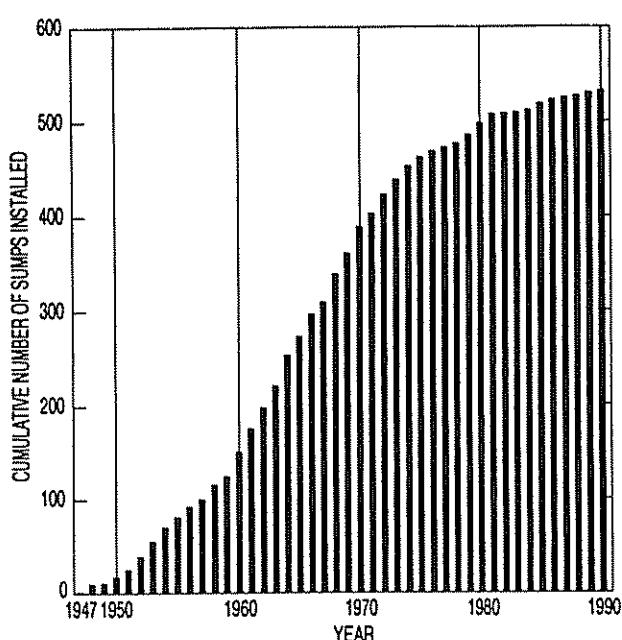

Figure 4. Continued.

**Figure 5.** Historical increase in number of drainwater sumps installed in the Imperial Valley.

mined for unfiltered samples from the last collection, and these data are given in the bottom row for each site in table 4. Data from the filtered sample are given in the preceding row.

Of the 15 sites, 14 showed visible evidence of recent irrigation or had measurable drainwater discharge during the period of monitoring. Sump S-142, at site 33, was not receiving drainwater flow during any of the sampling dates, and the soil's surface frequently showed no visible evidence of recent irrigation. Isotopic data for the winter period are believed to be anomalous—possibly owing to evaporation from the sump and absence of irrigation during this period until the sump was once again completely flushed prior to the April 10 collection.

## SURFACE-WATER DATA

### MONTHLY MONITORING AT SIX LOCATIONS

Surface-water samples from six locations were collected and analyzed in conjunction with monthly monitoring at the 15 drainwater sites. The data are given in table 5. The East Highline Canal represents irrigation water that is supplied to the Imperial Valley, and the New and Alamo Rivers and Trifolium Drain 1, where they discharge to the Salton Sea, represent the accumulated input of agricultural drainage

in the Imperial Valley. All samples from the monthly collections were filtered. Quarterly data also include analyses of unfiltered samples that were collected using the equal-width-increment method and composited in a churn splitter.

Chemical data for a single sample from San Felipe Creek also are given in table 5. The sample from San Felipe Creek was a grab sample collected immediately west of Highway 78 just south of the junction of Highways 78 and 86. This collection site is upstream from the cultivated part of the San Felipe Creek subbasin that is irrigated with Colorado River water. The channel contained extremely shallow flows and isolated pools when the sample was collected.

Comprehensive data for water samples from the Salton Sea are given and described in a later section of this report.

## HISTORICAL TRITIUM CONCENTRATIONS IN THE COLORADO RIVER

Tritium concentrations in surface water, ground water, and shallow soils were determined during this study to distinguish post-1950 irrigation water from older water in the Imperial Valley and to place time constraints on the percolation of irrigation water to subsurface drains. Historical tritium concentration data for the lower Colorado River at Imperial Dam (table 6) are essential to both objectives. The historical data were obtained from a national monitoring network operated by the USGS (Michel, 1989). All tritium concentrations are reported in picocuries per liter (pCi/L)—obtained by multiplying concentrations reported by the analyst in tritium units by 3.2. Annual average tritium concentrations, and concentrations adjusted for radioactive decay to 1988 (the year in which most drainwater, surface-water, and ground-water samples were collected for this study), are given in table 6. The average concentration of 90 pCi/L in 1988, which is based on the USGS monitoring of the Colorado River at Imperial Dam, can be compared with values of 82, 88, 90, and 96 pCi/L obtained for this study during August 1988 on water samples from the All-American and East Highline Canals.

## ALAMO RIVER DELTA SAMPLING

Aqueous-profile and surficial-sediment chemical data were obtained along a transect across the Alamo

River delta (figs. 2A, 3) from the mouth of the river to the Salton Sea to determine the location of the mixing zone between freshwater and saltwater and to ascertain any areal trends in selenium concentration in the sediment. The location of sample-collection sites and the selenium-concentration data from sediment samples are shown in figure 3. Sediment samples were collected, using either a small Ekman dredge or a piston corer, in August 1988 and February 1989. See Stewart and others (1992) for data from samples collected in February 1989 and for a description of analytical methods, precision, and reporting limits.

Water samples were collected from an airboat; a Van Dorn sampler was used in deep water, and a wide-mouth glass bottle was used in embayments where water depths were less than about 1 ft. In addition, specific conductance, temperature, pH, and dissolved oxygen were measured in the field with a multi-parameter probe. Sampling was done in August 1988, February 1989, and August 1989. Results of these field measurements for selected (1988) samples are given in table 7. The freshwater/saltwater interface occurs over a very narrow horizontal distance. The interface is shown by the vertical profile to be at delta site 10, about 200 ft from the levee on the left bank of the Alamo River, where freshwater is present above the more dense Salton Sea water.

## SELENIUM REDOX SPECIATION

Previous studies showed that a high proportion of selenium in the low-selenium water (that is, low in comparison with drainwater) from the Salton Sea was in highly reduced (negative oxidation) states (Cooke and Bruland, 1987). Also shown were high selenium concentrations (also, likely in reduced state) in surficial sediments from the Salton Sea (Schroeder and others, 1988), and high concentrations in drainwater that are consistent with selenium in the highly soluble oxidized (+6) state. These studies indicated the need for selenium redox-speciation analyses of water, especially near the Salton Sea. Several aqueous samples were analyzed for selenate (+6), for the less highly oxidized and less soluble selenite (+4), and for total selenium; selenium in negative and zero oxidation states was not determined. The proportion as highly oxidized selenate (+6) decreased from 60 percent on the freshwater side at the mouth of the Alamo River to below detection on the saltwater side in the Alamo River delta. At drilling site 8 (see next section of this report), ground water from piezometers in which selenium was present, albeit at low concentrations, contained small amounts of selenite (+4) but

no detectable selenate—in contrast to drainwater from the sump (S-417) at this site, in which 98 percent of the total selenium content (concentration was 275 µg/L) was selenate (Ann Maest, USGS, written commun., 1990).

## LITHOLOGY AND GROUND-WATER DATA

### LITHOLOGY AT THREE DRILLING SITES

Holes were drilled for installation of multiple-depth piezometers and suction-cup lysimeters at three sites in the Imperial Valley. The sites are located in the northern, middle, and southern parts of the valley (sites 8, 50, and 98 in fig. 2B) and are near the valley's topographic axis. The purpose of the drilling and sampling program was to determine changes in ground-water quality with depth and to ascertain the possible influence of shallow, regional ground water on drainwater quality.

A deep hole (depth of about 100-200 ft) was drilled at each location with a mud-rotary rig using irrigation water from nearby canals to make up the drilling fluid. Several 2-inch-diameter PVC piezometers with 5-foot perforated intervals were installed at each location. The annulus was backfilled with sand opposite the perforations, with bentonite pellets between the perforations, with grout above the shallowest perforation to within 3 to 5 ft of land surface, and with cement from above the grout to land surface. At the middle and southern sites, where spacing of perforated intervals was thought to be too close to permit installation of a good bentonite seal, a second, shallower hole was drilled and one piezometer was installed at a preselected depth.

The near-surface soils in Imperial Valley are fine grained; clay (particle size less than 0.004 mm) content ranged from about 70 percent at the northern drilling site to about 20 percent at the southern drilling site (table 8). The lithologic description in table 9 was prepared from the drill operator's observations of drilling characteristics, field observations on cuttings brought to the surface in the mud, grain-size analysis of cores shown in table 8, and geophysical logs (caliper, gamma ray, spontaneous potential, and single-point resistivity). A 2-foot split-spoon core was collected whenever field observations, including a perceived change in drill characteristics, indicated a possible significant change in texture from that of the overlying material.

The objective of drilling was to penetrate at least one thick clay-rich, low-permeability zone and place

piezometers in the more permeable material above and below this zone, thereby increasing the likelihood that the deepest piezometer tapped the shallow, regional ground-water system. This objective was readily achieved at the northern site, where the two deepest piezometers were separated from each other by a clay-rich zone extending from 85 to 181 ft below land surface (table 9). At the middle site, and especially at the southern site, numerous clay-rich layers were penetrated that are much thinner than those at the northern site. As a result, one or more piezometers were installed within the shallow, regional ground-water system at the middle and southern sites.

Water levels in the shallowest piezometers from the northern and middle sites were below land surface, and close to the altitude of the subsurface drains. However, in the 75- and 199-foot piezometers at the northern site and in the 71- and 95-foot piezometers at the middle site, ground water flowed at 1 L/min or more from the casing that extended about 2 ft above land surface. At both of the flowing (artesian) piezometers at the northern site, the ground water was heavily charged with carbon dioxide and had temperatures indicative of a higher than normal geothermal gradient. Numerous mudpots with escaping carbon dioxide are present beneath nearby parts of the Salton Sea and the Imperial Wildlife Management Area, and geothermal-resource development is prevalent in the area. The 75-foot piezometer always "resealed" itself a few weeks after sampling, but it could be induced to erupt again, several feet into the air, with minimal pumping and physical agitation of the water in the well casing. Water levels in all piezometers at the southern site, unlike conditions at the northern and middle sites, were near or a few feet below the depth of the drains.

A few piezometers were placed opposite clay-rich, low-permeability zones (as designated in table 9). After complete evacuation of the casing, recovery from these piezometers was very slow (about 1 L/hr); hence, it is believed that they were never completely purged (during the time of this study) of drilling fluid. The presence of small quantities of drilling fluid mixed with formation water in these samples is supported by reversal of the general pattern of decreasing tritium with increasing depth, and may be the indirect cause (by stimulating biological activity) of a slight odor of hydrogen sulfide that was observed when these wells were first pumped to remove stagnant water from the casing and annulus.

The holes for installation of as many as four multiple-depth ceramic-cup suction lysimeters (not all

the lysimeters produced water) were drilled using an air-rotary technique that eliminated the need for extensive development prior to sample collection. A very fine crystal-silica sand was placed opposite the cups, and coarse sand was placed immediately above and below each lysimeter. A bentonite seal was placed between each of the lysimeters. Installation of lysimeters at the southern site was unusually difficult. Collapse of the hole occurred during drilling because of the presence of thin, fine-sand and silt lenses and of wetness owing to nearby canals, ditches, a tailwater channel, and the sump. As a result, the chemical data from shallow depths at this location may be unduly influenced by the direct infiltration of comparatively fresh irrigation water, and thus the data are not representative of drainwater conditions in interior parts of the field.

The lysimeters are located next to the sump at a corner of the field at the southern and middle sites and along the edge of a field at the northern site. Partly because of access constraints and partly to avoid localized influences from irrigation, the piezometers were installed along elevated dirt roads a short distance from the fields.

## GROUND-WATER QUALITY

Ground-water-quality data from the lysimeters and piezometers in Imperial Valley are given in table 10. Water sampled from the lysimeters was effectively filtered during passage of the water from the soil through the ceramic cup. Samples from piezometers were filtered through a 0.45- $\mu\text{m}$  membrane in the field as the ground water was pumped directly from the casing. Noteworthy is the fact that a large quantity of carbonate precipitated almost immediately in the collection bottle as the supersaturated solutions from the two deepest piezometers at site 8 (the northern drilling site) degassed carbon dioxide. Much smaller quantities of carbonate also precipitated as deep ground-water samples were brought to the surface at site 50 (the middle drilling site).

## SOILS AND POREWATER DATA

Soil samples for chemical and tritium analyses were obtained by manually augering to depths of about 3 and 6 ft in fields at the 15 monthly drainwater-monitoring sites. These depths correspond to the maximum depth of cultivation (ripping by chisel) and to a common depth for subsurface-drain installation, respectively. Soils were recovered at the

head (H), middle (M), and tail (T) of the field—from directly above, midway between, and one-quarter the distance between drain laterals. Hence, S-417-T-18-50-6 designates a sample from the tail end of the field, at S-417, 50 ft from subsurface drain lateral 18, at a depth of 6 ft.

Cores from the three drilling sites are designated by depth below land surface. All solid-phase and soils-extraction data (tables 11-15) include the laboratory identification number used by the USGS to designate the sample analyzed.

## SHALLOW SOILS

Chemical analysis of soils from fields at the 15 sites was done to establish range in constituent concentrations and any possible relation between concentrations in soil and drainwater. Deionized-water extracts of soils (using a water-to-soil ratio of 5 to 1) were analyzed to ascertain the possible relation between extract and drainwater chemistry, and between extract and soil concentrations. Data are presented in tables 11, 12, and 13. The 40 samples in table 12 are laboratory splits (samples reprocessed and analyzed separately) for selected samples in table 11, and results can be compared between the tables.

## CORES

Cores were analyzed for comparison of concentrations of constituents (especially selenium) with concentrations in shallow soils. Data are presented in tables 14 and 15.

In addition, deionized-water extracts were obtained to provide a quality-assurance check on the entire extraction procedure by comparison to known concentrations in ground water. Comparison of the extract data in table 14 with the ground-water data in table 10 confirms the presence of some aqueous selenium in core extracts from depths below which selenium in ground water is absent (less than 1  $\mu\text{g/L}$ ). This indicates that a significant portion of the aqueous selenium extracted from the solid phase is an artifact of the storage and (or) extraction procedure itself, and this fact must be considered when interpreting the extract data from shallow soils in tables 11 and 12.

## TRITIUM IN SHALLOW SOILS

Tritium concentrations were measured in soil moisture (porewater), which ranged from 18 to 30

percent of the soil on a wet-weight basis. The analysis was done on porewater baked from the soil at a temperature of about 80°C. The purposes of these analyses were to determine possible spatial variation within fields and to estimate the rate at which shallow, subsurface water moves to the drains. The soils that were sampled were obtained from 8 of the 15 fields where drainwater was monitored monthly for 1 year. The results, which are given in table 16, can be compared with historical tritium concentration in irrigation water from the Colorado River (table 6) and with drainwater tritium concentrations (table 4).

## LABORATORY EXPERIMENTAL DATA

### EVAPORATIONS OF IRRIGATION WATER

In order to determine more accurately the selenium-to-chloride ratio in irrigation water, periodic samples from the East Highline Canal at its diversion from the All-American Canal were concentrated by evaporation in the laboratory and then analyzed. Water was reduced to as little as 2 percent of its original volume (final volume approximately 500 mL) by evaporation at 30-35°C, with continuous stirring, from large glass chromatography jars; the concentrated sample then was centrifuged prior to analysis. About 1 month was required to complete each evaporation sequence. Evaporations were carried out using both raw water and water acidified to a pH of approximately 3 by addition of nitric acid (except for the January 1989 evaporation sequence, in which hydrobromic acid was used but found to be contaminated by a small but significant quantity of chloride) prior to evaporative concentration. Low pH was maintained in the acid-treated water to prevent formation of calcium carbonate, which began to appear in the untreated water soon after evaporation commenced. Calcium sulfate precipitated during evaporation of both the acidified and untreated waters.

Calculated mean selenium-to-chloride weight (gravimetric) ratio for the most concentrated sample from eight evaporation studies during April-December 1989 (on the basis of analyses reported in table 17) is  $2.2 \times 10^{-5}$  in the nitric-acid-acidified concentrates (range  $1.7$ - $2.6 \times 10^{-5}$ ) and  $1.7 \times 10^{-5}$  in the untreated concentrates (range  $1.4$ - $2.3 \times 10^{-5}$ ). Presence of some selenium in the calcium carbonate (dissolved with nitric acid and diluted by addition of about 100 mL of deionized water) that formed during evaporation of the untreated water is indicated by data in table 17. However, mass-balance calculations to quantify the apportionment of selenium between aqueous and solid

phases should not be attempted because aqueous volumes (and precipitate weight) were only estimated, and the precipitate itself was only partially rinsed with deionized water prior to its dissolution with acid.

Analysis of both precipitates from one evaporation sequence using complete-mineral digestion techniques demonstrates that incorporation of selenium in the laboratory experiment is by calcium carbonate but not by calcium sulfate. Results of the comparison were as follows:

Element	Untreated evaporation	Acidified evaporation
Calcium (percent)	14	23
Sulfur (percent)	11	18
Selenium ( $\mu\text{g/g}$ )	6	<0.1

Note that other minerals, in addition to calcium sulfate and calcium carbonate, also are present (silica, for example) as indicated by lower calcium percentages than would be present in a pure phase of either of these two calcium-containing minerals.

#### DILUTIONS OF SEAWATER AND SALTON SEA WATER

Results of chemical analyses of water samples from the Salton Sea and the Pacific Ocean (near the San Diego coast), and of samples from both sources diluted by addition of deionized water are given in table 18. These data were obtained to provide quality assurance for chloride and bromide analyses over the range in concentrations present in the study area. The published average oceanic chloride-to-bromide weight ratio of 288 (Riley and Skirrow, 1975) can be compared with mean ratios of 317 in undiluted and 307 in diluted seawater calculated from the data in table 18. The measured chloride-to-bromide ratio in Salton Sea water was about 1,300 in both diluted and undiluted samples. The data in table 18 are from analysis of samples that were collected and archived for periodic later analysis; the dates given in the table correspond to the approximate periodic monthly spacing of the evaporation experiments described in the preceding section rather than the actual date of sample collection.

Analyses of major and selected minor constituents in filtered samples collected in October 1989 provide data for a comprehensive chemical comparison of seawater and water from the Salton Sea. Comparison between published and measured chemical concentrations in seawater provides an indication of the accuracy of saline-water analyses for this study.

Isotope data on grab samples collected during August 1988 from nearshore areas (fig. 2A) around the Salton Sea—at the Niland boat ramp, North Shore pier, Salton City pier, center of the south Salton Sea basin (the only site not close to shore), and between the Alamo and New River deltas—are given (in temporal order of collection) in table 18.

## BIOLOGICAL DATA

### BACKGROUND

Increased concern about trace-element and organic contaminant loading to the Salton Sea and nearby areas from the associated drainwater system led to this examination of possible contamination of these habitats. Sampling was done in 1986-87 during a reconnaissance investigation to assess concentrations of trace elements and selected pesticides. Chemical data and interpretations from the reconnaissance were published by Setmire and others (1990b). Elevated levels of selenium, boron, and DDT metabolites were found during the reconnaissance. These findings led to the decision to do a more detailed study during the following 3 years, at which time additional biological samples were collected to determine contaminant pathways and levels of exposure of organisms to contaminants.

### SAMPLING SITES

The location of sampling sites for collection of biological data is shown in figure 4, and sites are listed in table 19. The sites were chosen on the basis of ecological importance to fish and wildlife, relevance to exposure pathways, and strategic importance to tracking of contaminant sources. Priority was given to areas with high resource use, areas adjacent to high pesticide use, and areas of known high trace-element concentrations.

### SAMPLE COLLECTION AND PRESERVATION

The biological samples that were collected include 31 diverse species (or genera) representing all the trophic levels present in the Salton Sea area. The samples include vegetation, invertebrates, fish, amphibians, reptiles and reptile eggs, and birds and bird eggs. The species collected and the locations from which they were taken are listed in table 20. The procedures followed for collection of biological samples are those specified by USFWS (1985b). All bio-

logical samples were frozen after collection and stored frozen until analysis.

Vegetation was collected by hand from agricultural drainage ditches and from various locations in the Salton Sea where suitable habitat was provided by a rocky substrate. Algae were collected from several shore locations around the Salton Sea. Excess debris was removed from the algae by washing with Salton Sea water, after which the algae sample was placed in chemically cleansed jars. Cattail samples were collected from agricultural drainage ditches. Excess debris was removed from cattails by washing at the collection site with drainwater before placement of the sample in polyethylene bags for frozen storage.

Invertebrates, such as waterboatmen and amphipods, were collected using lighted activity traps. Pileworms were collected by washing sediment onto fine-meshed screens. Crayfish were collected using small seines. Some Asiatic river clams that were retrieved from rivers and drainage ditches (drains) were specimens transplanted from a section of the Colorado River in plastic-mesh cages; the others were native Asiatic river clams that were collected from rivers and drains by sifting sediment through a sieve. All clams were shucked and their contents were placed in chemically cleansed jars. All other invertebrate samples were composited whole and placed in chemically cleansed jars.

Small fish, including both predator and prey species, were collected using long-handled dip nets or seines. Mosquitofish and sailfin mollies were obtained from rivers, creeks, and drains. Longjaw mud-suckers were obtained from the Salton Sea. Bairdiella were salvaged soon after they had washed ashore from the Salton Sea near Salton Sea NWR Unit 1 (the southern unit). Orangemouth corvina were collected from the Salton Sea using gill nets. Bairdiella and corvina were wrapped in aluminum foil and placed in polyethylene bags before freezing. All other fish species were placed in chemically cleansed jars.

Bullfrogs were collected from the Alamo River, and spiny softshell turtles were collected at Vail 4 Drain and at Hazard Pond. Frogs were speared and placed in aluminum foil. Turtles were collected using fish-baited hoop nets. Samples of liver and fat were dissected from the turtles and placed in chemically cleansed jars. Egg contents from one of the female turtles were composited and placed in chemically cleansed jars.

Several water-bird species were collected from the Salton Sea itself and from various locations throughout the Imperial Valley including rivers, creeks, drainwater ditches, and freshwater impoundments. The birds were shot using a 12-gauge shotgun and steel shot. Livers and breast-muscle tissue were dissected from birds of the following species and placed in chemically cleansed jars: ruddy duck, northern shoveler, black-necked stilt, American coot, eared grebe, and white-faced ibis. Carcasses from the black-necked stilts were wrapped in aluminum foil and placed in polyethylene bags or in chemically cleansed jars. Black-necked stilt eggs were collected from nesting sites near the Salton Sea. Eggs were harvested and their contents placed in chemically cleansed jars. One Yuma clapper rail was salvaged from the Wister Unit of the Imperial Wildlife Management Area; its carcass was wrapped in aluminum foil and placed in a polyethylene bag.

## CHEMICAL CONCENTRATIONS

The inorganic and organic analytes determined in biological samples are listed in table 21. Inorganic concentrations are given in table 22. Organochlorine-insecticide and polychlorinated biphenyl (PCB) concentrations are given in table 23. The PCB data include total-PCB concentrations and concentrations for categories based on the number of chlorine atoms present and on the four-digit Arochlor number used to designate commercial mixtures of the PCB congeners. Polycyclic aromatic hydrocarbon concentrations are given in table 24.

<sup>1</sup>Sump removed in 1987.

<sup>2</sup>Sump removed in 1988.

**Table 2.** Data from Imperial Valley drainwater samples collected by the U.S. Geological Survey, May 16–20, 1988

[Location of sites shown in figure 2. Date: Eleven sites with no date shown were sampled in 1986 (see table 1 for results) but not sampled in 1988; Altitude of land surface in feet above or below (–) sea level. ft<sup>3</sup>/s, cubic foot per second; µS/cm, microsiemen per centimeter at 25°C; °C, degree Celsius; mg/L, milligram per liter; µg/L, microgram per liter; ---, no data. The analysis for each sample is displayed as one line on three consecutive pages]

<sup>1</sup>Filtered sample.

**Table 5.** Data from periodic sampling of streams, East Highline Canal, and Trifolium Drain 1, August 1988–August 1989

[In sampling-site designations, numbers in parentheses are U.S. Geological Survey streamflow-gaging station numbers (8-digit numbers) or latitude-longitude (15-digit numbers). Location of sites shown in figure 2.  $\mu\text{S}/\text{cm}$ , microsiemen per centimeter at 25°C; °C, degree Celsius; mg/L, milligram per liter;  $\mu\text{g}/\text{L}$ , microgram per liter; ft, foot; mm, millimeter; pCi/L, picocurie per liter. —, no data. The analysis for each sample is displayed as one line on six consecutive pages]

Date	Time	Gage height (ft)	Discharge, mean daily ( $\text{ft}^3/\text{s}$ )	Spec. conductance ( $\mu\text{S}/\text{cm}$ )	pH (standard units)	Temperature, water (°C)	Calcium, total recoverable (mg/L as Ca)	Calcium, dissolved (mg/L as Ca)	Magnesium, total recoverable (mg/L as Mg)

**Table 9.** Lithologic description and perforated intervals for piezometers in the Imperial Valley

[Depth of clay-rich, low-permeability zones indicated in italics. Perforated interval: Asterisk indicates that piezometer is placed in a separate hole. ft, foot; cm, centimeter; mm, millimeter]

Depth (ft)	Perforated interval (ft)	Lithologic description
<b>S-417 (Northern Site)--Site 8</b>		
0-69	29-34 49-54	Clay and fine silt; increase in silt with depth; invertebrate shells near 25 ft; moderate brown (5YR4/4) trending to dark yellowish brown (10YR4/2) at bottom of interval.
69-85	70-75	Silt and fine sand; dark-gray or black thin stringers or small blebs in brown matrix
85-181		Clay and silt; moderate yellowish brown (10YR4/2) in top 20 ft of interval to olive gray (5Y4/1) in bottom 20 ft; olive-gray (5Y4/1) to greenish-gray (5GY6/1) thin (<1 cm) horizontal and vertical (up to several centimeters in length and a few millimeters in diameter) bands in dark-yellowish-brown (10YR4/2) matrix in core from 140-142 ft.
	194-199	Fine to medium sand; numerous small (1-3 mm) <i>Turritella</i> shells in core from 195-197 ft.
<b>S-154 (Middle Site)--Site 50</b>		
0-21		Clay and silt with small amount of fine sand at 16-18 ft; dark yellowish brown (5-10YR4/2-4)
21-32	23-28*	Very fine sand, clay, and silt.
32-34		Thin clay layer.
34-42	35-40	Very fine sand, clay, and silt similar to material from 20-32 ft
42-64	50-55	Silt and clay; moderate yellowish brown (5-10YR4-5/4).
64-76	66-71	Silt; dark yellowish brown (5-10YR3-4/2).
76-80		Thin clay layer.
80-96	90-95	Silt similar to material from 64-76 ft.
96-102		Clay and fine silt; dark yellowish brown (5-10YR4/2-4); numerous very small (<1 mm) <i>Turritella</i> shells in core from 100-102 ft
<b>S-371 (Southern Site)--Site 98</b>		
0-18		Silt and clay with silt increasing with depth; silt and fine sand lens from 7 to 9 ft; dark yellowish brown (10YR4/2) at top grading to moderate brown (5-10YR4-5/4) at bottom.
18-25	18-23	Unsorted fine sand, silt, and clay; moderate brown (5YR4/4).
25-74	34-39* 44-49 60-65	Numerous thin (up to a few feet thick) strata alternating between silt and clay, clay and silt, and fine sand and silt; dark yellowish brown (10YR4-5/2-4)
74-103		Clay and silt; numerous 1-mm gastropod and <i>Turritella</i> shells in core from 80-82 ft; moderate brown (5-10YR4-5/4).
103-114	109-114	Fine to medium sand.

**Table 10.** Data from lysimeters and piezometers at three sites in the Imperial Valley

[Perforated interval and water level in feet below land surface (negative water-level values, including <0, above land surface). Altitude of land surface in feet above or below (-) sea level.  $\mu\text{S}/\text{cm}$ , microsiemen per centimeter at  $25^\circ\text{C}$ ;  $^\circ\text{C}$ , degree Celsius; mg/L, milligram per liter,  $\mu\text{g}/\text{L}$ , microgram per liter; pCi/L, picocurie per liter; —, no data; <, actual value less than value shown. The analysis for each sample is displayed as one line on four consecutive pages]

Perforated interval	Latitude (north)	Longitude (west)	Date	Time	Water level	Altitude of land surface	Specific conductance ( $\mu\text{S}/\text{cm}$ )	pH (standard units)	Temperature, water ( $^\circ\text{C}$ )	Calcium (mg/L as Ca)

**Table 11.** Selenium and water-extractable sulfate, chloride, and selenium concentrations in soils from 15 fields

[Soils data on dry-weight basis; aqueous data are from analysis of extract using 5 to 1 ratio of water to soil. See text (p. 12-13) for description of soil identifier. Concentrations in ppm (parts per million) and ppb (parts per billion). Laboratory standard is a soil from the San Joaquin Valley. <, less than indicated reporting limit; --- designates insufficient sample for analysis]

**Table 12.** Arsenic, selenium, and boron, and water-extractable sulfate, chloride, and selenium concentrations in soils from 15 fields

[Soils data on dry-weight basis; aqueous data are from analysis of extract using 5 to 1 ratio of water to soil. Concentrations in ppm (parts per million) and ppb (parts per billion). See text (p. 12-13) for description of soil identifier; D in soil identifier designates a duplicate analysis. Laboratory standard is a soil from the San Joaquin Valley]

Soil identifier	Soil				Water extract			
	Laboratory number	Arsenic (ppm)	Selenium (ppm)	Boron (ppm)	Laboratory number	Sulfate (ppm)	Chloride (ppm)	Selenium (ppb)

**Table 19.** Biological sampling sites for the detailed study of the Salton Sea area

[Location of sites shown in figure 4]

Site number	Description
<b>Salton Sea</b>	
B1	Salton Sea National Wildlife Refuge--Unit 1
B2	Poe Road
B3	U.S. Navy test base
B4	Salton City
B5	Salton Sea Beach
B6	Desert Shores
B7	Desert Beach
B8	Bob's Playa River Marina
B9	Bombay Beach
B10	S Lateral Drain outlet
B11	Alamo River delta
B12	Red Hill Marina
B13	Obsidian Butte
B14	Bowles Road
B15	New River delta
B16	Whitewater River delta
<b>Rivers and Creeks</b>	
B17	New River at Rio Bend
B18	Alamo River at Garst Road
B19	San Felipe Creek
B20	Salt Creek
B21	Colorado River at Palo Verde
<b>Drainwater Ditches</b>	
B22	Trifolium 5
B23	Trifolium 13
B24	Trifolium 14
B25	Vail Cutoff
B26	Vail 4
B27	Vail 4A
B28	Vail Drain at New River
B29	S Lateral
B30	Z Lateral
B31	81st Street
B32	Johnson Street
<b>Freshwater Impoundments</b>	
B33	Shady Acres Duck Club
B34	RH Pond
B35	HQ Pond
B36	Reidman Pond
B37	Hazard Pond
<b>Imperial Valley</b>	
B38	South Brawley
B39	McKendry Road

**Table 20.** Biotic samples collected from sites in the study area

[Sites described in table 19]

Species	Sample	Sites
Blue-green algae ( <i>Myxophyceae</i> )	Vegetation Composite	B32
Filamentous green algae ( <i>Chaetomorpha</i> sp.)	Composite	B1, B3, B4, B5, B6, B7, B8, B9, B12, B13, B14, B31
Tubular green algae ( <i>Enteromorpha</i> sp.)	Composite	B1, B2, B3, B4, B5, B6, B7, B8, B9, B12, B13, B14, B31
Common cattail ( <i>Typha latifolia</i> )	Whole plant	B19, B20, B30, B31, B32
Periphyton	Composite	B1
<b>Invertebrates</b>		
Asiatic river clam ( <i>Corbicula fluminea</i> )	Soft-tissue composite	B1, B15, B16, B17, B18, B21, B23, B24, B25, B26, B28, B30, B32
Crayfish ( <i>Procambarus clarki</i> )	Whole body	B1, B11, B15, B24, B37
Pelagic invertebrate "mixture"	Composite	B1, B23
Pileworm ( <i>Nereis succinea</i> )	Composite	B1, B11, B27
Waterboatman ( <i>Corixidae</i> )	Composite	B11, B15, B18
<b>Fish</b>		
Bairdiella ( <i>Bairdiella icistia</i> )	Whole body	B10
Longjaw mudsucker ( <i>Gillichthys mirabilis</i> )	Whole body	B15
Mosquitofish ( <i>Gambusia affinis</i> )	Whole body	B15, B19, B20, B31, B32, B37
Orangemouth corvina ( <i>Cynoscion xanthulus</i> )	Whole body	B1
Redfin shiner ( <i>Lythrurus umbratilis</i> )	Whole body	B16
Sailfin molly ( <i>Poecilia latipinna</i> )	Whole body	B1, B16, B17, B19, B20, B30, B31, B32, B37
Tilapia ( <i>Tilapia zilli</i> )	Whole body	B1, B15, B16, B17, B22, B37
<b>Amphibians</b>		
Bullfrog ( <i>Rana catesbeiana</i> )	Whole body	B18
<b>Reptiles</b>		
Spiny softshell turtle ( <i>Trionyx spiniferus</i> )	Fat/liver/egg	B26, B37
<b>Birds</b>		
American coot ( <i>Fulica americana</i> )	Liver	B15, B16, B17, B25, B37
Barn owl ( <i>Tyto alba</i> )	Muscle	B17
Black-necked stilt ( <i>Himantopus mexicanus</i> )	Carcass/egg	B1, B11, B15, B16, B17, B24, B25, B29, B34, B36, B37, B39
Cattle egret ( <i>Bubulcus ibis</i> )	Muscle	B17, B37
Double-crested cormorant ( <i>Phalacrocorax auritus</i> )	Muscle	B17, B37
Eared grebe ( <i>Podiceps nigricollis</i> )	Liver/muscle	B13, B15
Great blue heron ( <i>Ardea herodias</i> )	Muscle	B1
Herring gull ( <i>Larus argentatus</i> )	Muscle	B37
Northern shoveler ( <i>Anas clypeata</i> )	Liver/muscle	B1, B11, B16, B33, B37
Ruddy duck ( <i>Oxyura jamaicensis</i> )	Liver/muscle	B1, B15, B17, B24, B26, B35, B37
White-faced ibis ( <i>Plegadis chihi</i> )	Liver/muscle	B38
Yuma clapper rail ( <i>Rallus longirostris yumanensis</i> )	Carcass	B29

**Table 21.** Chemicals analyzed for in biota in the detailed study of the Salton Sea area

Inorganic Analytes			
Aluminum (Al)	Cadmium (Cd)	Manganese (Mn)	Strontium (Sr)
Antimony (Sb)	Chromium (Cr)	Mercury (Hg)	Thallium (Tl)
Arsenic (As)	Copper (Cu)	Molybdenum (Mo)	Tin (Sn)
Barium (Ba)	Iron (Fe)	Nickel (Ni)	Vanadium (V)
Beryllium (Be)	Lead (Pb)	Selenium (Se)	Zinc (Zn)
Boron (B)	Magnesium (Mg)	Silver (Ag)	

Organic Analytes			
Aldrin	Dicofol	Biphenyl CL-4	Naphthalene
Benzene hexachloride (BHC)	Dieldrin	Biphenyl CL-5	Acenaphthene
beta-BHC	Endosulfan I	Biphenyl CL-6	Fluorene
delta-BHC	Endosulfan II	Biphenyl CL-7	Phenanthrene
gamma-BHC	Endosulfan sulfate	Biphenyl CL-8	Anthracene
alpha-Chlordane	Endrin	Biphenyl CL-9	Fluoranthene
cis-Chlordane	Heptachlor	PCB 1016	Pyrene
gamma-Chlordane	Heptachlor epoxide	PCB 1221	Benzo (a) anthracene
trans-Chlordane	Hexachlorobenzene	PCB 1232	Chrysene
Chlorthal-dimethyl (DCPA)	Lindane	PCB 1242	Benzo (b) fluoranthene
o,p'-DDD	Methoxychlor	PCB 1248	Benzo (k) fluoranthene
p,p'-DDD	Mirex	PCB 1254	Benzo (a) pyrene
o,p'-DDD	cis-Nonachlor	PCB 1260	Benzo (e) pyrene
p,p'-DDE	trans-Nonachlor	Total PCB	Perylene
o,p'-DDT	Oxychlordane	Tetradifon	Indeno (1,2,3-cd) pyrene
p,p'-DDT	Biphenyl CL-2	Toxaphene	Dibenz (ah) anthracene
Total DDT	Biphenyl CL-3		Benzo (ghi) perylene

**Table 22.** Inorganic chemical analysis and moisture content for biotic samples collected during 1988-90 from the Salton Sea and associated drainwaters and rivers

[All chemical data reported in micrograms per gram, dry weight. <, less than indicated reporting limit; ---, not determined. The analysis for each sample is displayed as one line on three consecutive pages. NWR, National Wildlife Refuge]

Record number	Sample number	Species	Matrix	Percent moisture	Sil-ver	Alu-minum	Arsenic

**Table 23.** Organic chemical analysis, moisture content, and lipid content for biotic samples collected during 1986-90 from the Salton Sea and associated drainwaters and rivers

[All chemical data reported in micrograms per gram, wet weight. DDD, dichlorodiphenyldichloroethane; DDE, dichlorodiphenylethylene; DDT, dichlorodiphenyltrichloroethane; o,p', ortho,para prime; p,p' para,para prime; BHC, benzene hexachloride; DCPA, dimethyltetrachlorophthalate; BI PH CL, biphenyl chemical structure with number of chlorine substituents designated; PCB, polychlorinated biphenyls with Arochlor numbers; <, less than indicated reporting limit; ---, not determined. The analysis for each sample is displayed as one line on six consecutive pages. NWR, National Wildlife Refuge]

**Table 24.** Polycyclic aromatic hydrocarbon concentration, moisture content, and lipid content for single samples of crayfish and tilapia collected in the study area in 1987

[All chemical data reported in micrograms per gram, wet weight; NWR, National Wildlife Refuge. <, less than indicated reporting limit]

Site No. Location	B1 Salton Sea NWR--Unit 1	B37 Hazard Pond
Sample number . . . . .	LNSS87-20	LNSS87-25
Species . . . . .	Crayfish	Tilapia
Matrix . . . . .	Whole body	Whole body
Percent moisture . . . . .	72.2	65.4
Percent lipid . . . . .	.69	11.2
<b>Compound name</b>		
Naphthalene . . . . .	<0.02	<0.02
Acenaphthene . . . . .	<.02	<.02
Fluorene . . . . .	<.02	<.02
Phenanthrene . . . . .	.035	<.02
Anthracene . . . . .	<.02	<.02
Fluoranthene . . . . .	<.02	<.02
Pyrene . . . . .	<.02	<.02
Benzo(a)anthracene . . . . .	<.02	<.02
Chrysene . . . . .	<.02	<.02
Benzo(b)fluoranthene . . . . .	<.02	<.02
Benzo(k)fluoranthene . . . . .	<.02	<.02
Benzo(a)pyrene . . . . .	<.02	<.02
Benzo(e)pyrene . . . . .	<.02	<.02
Perylene . . . . .	<.02	<.02
Indeno(1,2,3-cd)pyrene . . . . .	<.02	<.02
Dibenzo(a,h)anthracene . . . . .	<.02	<.02
Benzo(g,h,i)perylene . . . . .	<.02	<.02
